## FAMILIES OF AMERICAN MEN OF SCIENCE <sup>1</sup>

IN a series of articles entitled "A Statistical Study of American Men of Science," printed in *Science* in 1906 and 1910 and as an appendix to the second edition of "The Biographical Directory of American Men of Science," methods were explained by which the thousand leading scientific men of the United States had been selected and arranged in the order of the merit of their work. Studies were made of the measurement of scientific performance, of the origin and distribution of scientific men, and of the changes which occurred during an interval of several years. Data have now been gathered in regard to the families of the men of science previously selected. In our present state of ignorance a statistical study of any homogeneous and objectively chosen group should be of value, both as a contribution to psychological and vital statistics in general and for comparison with other groups which may be similarly studied. Scientific men form a desirable group for such study as, on the one hand, they may be assumed to be willing and competent to supply the information and, on the other hand, knowledge concerning the conditions favorable to scientific performance may have important practical applications.

Of one thousand one hundred and fifty-four scientific men from whom information in regard to their families was requested 1,036 replied and 118 did not. Of the replies 16 were blank, sometimes accompanied by the explanation that the information was not readily attainable or the like, 7 were to the effect that the information would be sent later or the like, 13 were received too late, 25 were very im-

perfect, 975 were usable and in most cases complete. This is an unusually full reply to a questionnaire. For example, in answer to an inquiry in regard to noteworthy relatives addressed to 467 fellows of the Royal Society, Sir Francis Galton received 207 useful replies, and the completely available returns "scarcely exceeded 100." In such cases it is desirable that returns should be complete in order to avoid the selection of a special class. Thus, when people are asked whether they have noteworthy relatives, those having them are more likely to reply than others, and the percentage of positive replies may give no definite information in regard to the frequency. In the present case it appears, from examination of the names of the ten per cent, who failed to reply, that there was no group that would affect appreciably the result of the inquiry.

### I. ORIGIN, HEREDITY AND PERFORMANCE

In the previous articles statistics were given in regard to the birthplace of the scientific men, and data are now at hand

in regard to the nationality and race of their parents. Of the thousand scientific men first selected 126 were born abroad—34 in Canada, 38 in Great Britain and 19 in Germany. Table I. gives the nationality of the parents of 917 leading scientific men. Six hundred and twenty-eight, or more than two thirds, have both parents of native American (United States) birth, 23 others have an American father and 42 an American mother, foreign men having married American women more frequently than the reverse. In 165 cases both parents are foreign born and of the same nationality. Including Americans there are 124 marriages in which the nationality of the parents was mixed, but they were largely British. The American-born parents are mainly of British and New England descent; of foreign-born parents, 137 fathers and an equal number of mothers are English, Scotch, Irish or Canadian. Germany contributes 77 fathers and 66 mothers. Other nations contribute in all 52 fathers and 44 mothers—fairly equally distributed among Norwegians, Swedes, Russians, Dutch, French and Swiss, with several from Denmark, Italy and Japan. The parents of American men of science are thus predominantly British-American, with an admixture of nearly 8 per cent. of Germans and about 5 per cent. from other nationalities.

Twelve and six tenths per cent. of our leading scientific men are foreign born, 12.6 per cent. are native born of foreign-born parents, and 7.1 per cent. have one foreign-born parent. In the general population of the United States 14 per cent. of the people are foreign born, 13.5 have both parents foreign born and 6.7 have one parent foreign born. The foreign born and those of foreign-born parentage thus contribute less, but only slightly less, than the native population to scientific productivity. There is a great difference in the different nationalities. Those born in Great Britain contribute 1.2 per cent.

to the population and 3.4 per cent. to our scientific men; Germany contributes 2.7 per cent. to the population and 1.9 per cent. to the scientific men; Russia 1.7 to the population and 0.6 to the scientific men; Italy 1.5 to the population and 0.1 to the scientific men. These differences are not, however, necessarily due to any racial superiority of the British and Germans. Men have been called from these countries to scientific positions here or have come to seek them, and in general a larger proportion of their immigrants have been from the educated class. In my own science men so distinguished as Professor Münsterberg from Germany and Professor Titchener from England have accepted chairs of psychology in our universities. It is most unfortunate for us that this movement appears to have ceased. Between 1903 and 1910 only one scientific man of high distinction was called to this country, whereas nine leading scientific men returned to their native countries.

We could and should see to it that the foreigners coming to the United States contribute their share of men of performance. From the point of view of national selfishness nothing could be more profitable than to add to the community as many foreign men of distinction as would come for five or ten thousand dollars a year, and as many young men of promise as would come for one or two thousand dollars a year. Such men are already selected and their education is paid for. We have paid for the education of some 150,000 physicians to obtain at most 1,000 who are competent to advance medical science. The services of this thousand are probably worth as much as those of all the others combined, so if we divide equally the cost of bringing up and educating these physicians, the cost of a man competent to advance science is perhaps \$500,000 and his value is far greater. Such men we can obtain from abroad free of

cost beyond the payment for their living, which must be paid equally to those who are educated and selected at our own expense. Not only the men themselves, but their descendants also are assets to the country of incalculable value. From the point of view of the world at large, it is probably an advantage to bring men of distinction and of promise to this country, as this tends to promote friendly international relations and good-will, and because, the wealth being greater here and the competition less, we should be able to give better opportunity to the men. The war has placed on us great responsibility; we should provide for those debarred from advancing science, scholarship and art at home.

While it is comparatively easy to determine the nationality of scientific men and of their parents, it is almost impossible to determine their race. Indeed, a consideration of the subject leads to a realization of the complexity of the racial descent of the peoples forming the nations of western Europe and America. There are 13.5

families stated to be Jews. Of 71.5 German families, 8 are Jews; of 6 Russian families, 5 are Jews; among 660.5 native American families, there is only one Jewish parent. There may be some unrecorded cases; the number of native-born scientific men of Jewish family is smaller than might have been anticipated. Two families are Japanese; none is known to be of Negro or of North American Indian descent.

The scientific men have been divided into four groups in accordance with the merit of their performance. These are: I. those among the leading hundred of our scientific men; II. those among the second and third hundreds; III. those below this rank in the thousand; and IV. those who in the second arrangement fell below the thousand. As shown in the previous paper, the first three groups cover about equal ranges of merit, and this also holds in a general way for the fourth group. In Table II. is given the nationality of the parents of the scientific men in accordance with these grades. Those of American parentage are of average standing; those of British parentage are below and those of German parentage are above the average. Those of other nationalities are slightly above the average. Among the leading hundred men of science seven are of Jewish family. The Jewish race thus appears to show superior intellectual ability. The differences in the other nationalities and races are so small as to indicate practical equality. The slight

superiority of the Germans is due to several men who have come to this country to fill scientific positions, half of whom are of Jewish descent.

The occupations of the fathers of 885 scientific men are given in Table III. Forty-three per cent. belong to the professional classes; 21.2 per cent. to the agricultural classes and 35.7 per cent. to the manufacturing and business classes. In the United States in 1850, 3.1 per cent. of white men having occupations were in the professions; 44.1 were engaged in agriculture, and 34.1 in trade, transportation, manufacturing and mechanical pursuits. The professional classes have thus contributed in proportion to their numbers about fourteen times as many scientific men as the others, the agricultural classes only half as many as the manufacturing and trading classes. The farm not only produces relatively fewer scientific men, but a smaller proportion of them are of high distinction and a larger proportion are in the lowest group. This traverses a common belief, as voiced, for example, by Dr. Charles W. Eliot, when he writes:

The country breeding gives a vigor and an endurance which in the long run outweigh all city advantages, and enable the well-endowed country boys to outstrip their city-bred competitors.<sup>2</sup>

The writer showed, however, in the previous paper that in proportion to their population cities have produced twice as many scientific men as the country.

The four professions of divinity, medicine, law and teaching, with a fifth group composed of the remaining professions—engineering, fine arts, journalism, the government service, etc.—contribute numbers of scientific men not far from equal. According to the census of 1850, the numbers of the four learned professions were: Clergymen, 26,842; lawyers, 23,939; physicians, 40,765; men teachers, 30,530.

<sup>2</sup> "Family Stocks in a Democracy," American Contributions to Civilization, 1898.

For each thousand of their members, they contributed scientific men as follows:

Clergymen .....	3.3
Lawyers .....	2.5
Teachers .....	2.4
Physicians .....	1.6

Clergymen, therefore, have the best record, and physicians the worst. Yet at that period there was supposed to be a conflict between science and theology, and the work of the physician is, or should be, allied to, if not identical with, that of the man of science. But in the middle of the last century the clergymen were likely to be better educated and more closely identified with the colleges than the physicians. The lawyers and the teachers were equally productive, but college professors—of whom there were only 943 in 1850—are far before any other class. The group of "other professions" is too ill defined to permit statistical treatment. In the census of 1850, mechanics who ran engines were called engineers and included among the professions. It will be noted from the table that lawyers and teachers have contributed the largest percentage of scientific men of high distinction, but the differences are not so large as to be significant.

As it is much easier to determine nationality than race, so occupation can be stated more readily than social position. It would be desirable to know the social connections and incomes of the fathers of scientific men at the period when their sons were educated, but such information is not at hand. Men in the same profession have very different social environments; in manufacturing and trade a man may be an artisan or a multi-millionaire. It is, however, clear that a majority of scientific men come from the so-called middle and upper classes. Not very far from half of them are supplied by the professional classes, forming about one thirtieth of the population, and undoubtedly they tend to be sons of the more

successful professional men. Under manufacturing and trade all sorts of occupations are included, but only a small part of the fathers belong to the class of artisans and still fewer to the class of clerks. Most of them own their own business, which may be anything from a small shop in a university town<sup>3</sup> to the control of a railway system. Not a single scientific man is recorded as coming from the class engaged in domestic service, nor is any known to be the son of a day laborer, even of the higher grades. Agriculture includes agricultural laborers, but the fathers of the scientific men usually owned their own farms, and were probably in the main the farmers of the better class with relatives among professional men. Our farming population belongs chiefly to a yeoman class, not to a peasant class such as forms nine tenths of the population of Russia.

The earlier studies of scientific men made by De Candolle and Galton and the groups treated by Odin and Ellis yield results in regard to the origin of men of performance comparable with those here given. De Candolle<sup>4</sup> found that of 100 foreign associates of the Paris Academy of Sciences, 41 came from noble and wealthy families, 52 came from the middle class and 7 from the working class. Galton<sup>5</sup> found that of 96 contemporary leading men of science none came from the artisan and peasant classes. Odin<sup>6</sup> found that of 823 French men of letters, 65 per cent.

<sup>3</sup> A notable case is of three brothers who have attained scientific distinction. They obviously had inherited ability, but the opportunity to exhibit it in scientific research was probably due to the fact that their father's shop was in a university town.

<sup>4</sup> "Histoire des Sciences et des Savants depuis deux Siècles," Genève, 1873.

<sup>5</sup> "English Men of Science," London, 1874; New York, 1875.

came from the nobility and governing classes, 23 per cent. from the professions, 12 per cent. from the commercial and middle classes and 16 per cent. from the lower classes. Ellis<sup>7</sup> found that of 829 British men of genius 18.5 per cent. came from the nobility and upper classes, 41.3 per cent. from the professions, 31.2 from the manufacturing and commercial classes, 6 per cent. from the yeomen and farmers and 2.5 from the artisan and laboring classes.

The working classes outnumbered the nobility a hundredfold, but produce only one quarter as many men of performance. If the working classes have equal ability and if they had been given equal opportunity, instead of a hundred scientific men of the rank of the foreign associates of the Paris Academy there would have been forty thousand. It may be that the peasant and artisan classes in European countries are separated from the upper classes by an inferior heredity; but that is scarcely the case in America. Five or ten generations back most of us have ancestors of nearly the same average physical, intellectual and social condition; any selection for ability within this short period must be slight and transient.

It is evident that what a man can do depends on his congenital equipment. How far what he does do depends on his environment and how far on his congenital equipment, or how far his congenital equipment depends on that of his parents and his family line of descent, we do not know. Most sociological writers and some biologists are confused in their use of the concept of heredity. When there is discussion of the relative influence on performance of heredity and environment, by heredity there is sometimes understood the original constitution of the individual and sometimes his resemblance to parents and other relatives. It

<sup>7</sup> "A Study of British Genius," London, 1904.

is conceivable that the original constitution of son and father might be exactly the same and yet the individual be so plastic to environment that under different conditions there would be but slight similarity between their performances. It is also conceivable that there might be no similarity between the original constitutions of son and father, and yet the performance of each be determined by his original constitution almost without influence from environment. Under which of these extreme hypotheses would the current sociologist call heredity strong or weak? The word heredity should be reserved for resemblance due to a common germ plasm and some other word found for the constitution of the fertilized ovum or zygote; perhaps the best that can be done is to use this uncouth word. We can then discriminate between the two distinct questions: What is the resemblance between the zygotes of two brothers? How far does the zygote of an individual determine his performance as an adult?

The distinctions are of vast importance for the organization of society. If men of performance could only come from superior family lines, this would be a conclusive argument for a privileged class and for a hereditary aristocracy. If the congenital equipment of an individual should prescribe completely what he will accomplish in life, equality of opportunity, education and social reform would be of no significance. Such an extreme position, though it is approached by men with so much authority as Sir Francis Galton, Professor Karl Pearson, Dr. F. A. Woods, Dr. C. B. Davenport and Professor E. L. Thorndike, is untenable. Equally extreme in the opposite direction is M. Odin's aphorism "Genius is in things not in men," or the not uncommon opinion that almost anything can be done with a child by training and education. It is a problem of degree and of circumstance, a scientific question that could

probably be solved within a reasonable time if as much intelligence and money were devoted to it as to one of the bureaus of the Department of Agriculture.

In the meanwhile we must do the best we can with the material at hand, even though the interpretation is in nearly all cases ambiguous. It is here shown that 43 per cent. of our leading scientific men have come from the professional classes. We may conclude that more than one half of our men of science come from the one per cent. of the population most favorably situated to produce them. The son of a successful professional man is fifty times as likely to become a leading scientific man as a boy taken at random from the community. My data also show that a boy born in Massachusetts or Connecticut has been fifty times as likely to become a scientific man as a boy born along the southeastern seaboard from Georgia to Louisiana. They further show that a boy is fifty times as likely to do scientific work as a girl. No negro in this country has hitherto accomplished scientific work entitling him to be included among our leading thousand scientific men. A boy from the professional classes in New England has a million chances to become a scientific leader as compared with one chance for a negro girl from the cotton fields.

These great differences may properly be attributed in part to natural capacity and in part to opportunity. When it is asked how far the result is due to each of these factors, the question is in a sense ambiguous. It is like asking whether the extension of a spiral spring is due to the spring or to the force applied. Some springs can not be extended a foot by any force; no spring can be extended without force. The result depends on the relation between the constitution of the spring and the force applied. If the 174 babies born in Massachusetts and Connecticut who became leading scientific men had been exchanged with babies born in the south, it

seems probable that few or none of them would have become scientific men. It may also be the case that few or none of the babies from the south transplanted to New England would have become scientific men, but it is probably true that a nearly equal number of scientific men would have been reared in New England. It is certain that there would not have been 174 leading scientific men from the extreme southern states and practically none from Massachusetts and Connecticut. If the stock of the southern states remains undiluted, it may, as social conditions change, produce even more scientific men per thousand of its population than New England has hitherto produced. In the first list of the thousand leading scientific men, Massachusetts produced 109 and Connecticut 87 per million of their population. Of the younger men added to the list in the second arrangement under comparable conditions, Massachusetts produced 85 and Connecticut 57. The other North Atlantic states failed in like measure, while the central states show a gain—Michigan from 36 to 74, Minnesota from 23 to 59, etc. These changes must be attributed to an altered environment, not to an altered racial stock. Japan had no distinguished scientific men a generation ago and China has none now, but it may be that in a few years their contributions to science will rival ours.

A Darwin born in China in 1809 could not have become a Darwin, nor could a Lincoln born here on the same day have become a Lincoln had there been no civil war. If the two infants had been exchanged there would have been no Darwin in America and no Lincoln in England. Darwin was a member of a distinguished family line possessing high natural ability and the advantages of opportunity and wealth. Lincoln had no parental inheritance of ability or wealth, but he too had innate capacity and the opportunity of circumstance. If no infants had been

born with the peculiar natural constitutions of Darwin and Lincoln, men like them could not have been made by any social institutions, but none the less the work they did might have been accomplished by others and perhaps their fame would have been allotted to others. There may have been in England other family lines equal in natural ability to the Darwins and in this country other individuals as well constituted as Lincoln, but undistinguished from lack of opportunity. It is still more probable that such conditions obtain in Russia and in China, in whose graveyards there may lie innumerable "mute inglorious" Miltons, Lincolns and Darwins.

The most exceptional ability may be suppressed by circumstances; but it can sometimes deal with them on equal or perhaps superior terms. Thus the writer has pointed out how widely distributed in race, age and performance are the most distinguished men who have lived.<sup>8</sup> When we turn from the most eminent men to those next in rank, we may doubt whether their natural ability has not been equaled by thousands who have not attained distinction. Among the two hundred most eminent men who have lived in the history of the world are: Napoleon III., Nero, Fox, Julian, Fénelon, Clive, Alberoni, Bentley and Gerson. It is quite conceivable that there are at present living in the United States hundreds or thousands of men having as great natural ability as these. There may be a hundred thousand men and women having the natural and specific ability of the thousand in this country who have accomplished the best scientific work.

President A. Lawrence Lowell has remarked that we have a better chance of rearing eaglets from eagles' eggs placed under a hen than from hen's eggs placed in an eagle's nest. But it is also true that

<sup>8</sup> "A Statistical Study of Eminent Men," *The Popular Science Monthly*, 1903.

we have a better chance of raising tame eaglets in a chicken coop than in an eyrie. The difference between a man uninterested in science and a scientific man is not that between a chicken and an eagle, but that between an untrained chicken and a trick cock. Some cockerels can be trained better than others, but there are innumerable cockerels that might be trained and are not.

The son of a scientific man may on the average have the inherited ability which would make him under equally favorable circumstances twice, or ten times, or a hundred times, as likely to do good scientific work as a boy taken at random from the community. The degree of advantage should be determined. It surely exists, and the children of scientific men should be numerous and well cared for. But we can do even more to increase the number of productive scientific men by proper selection from the whole community and by giving opportunity to those who are fit. Galton finds in the judges of England a notable proof of hereditary genius. It would be found to be much less in the judges of the United States. It could probably be shown by the same methods to be even stronger in the families conducting the leading publishing and banking houses of England and Germany. As I write, the death is announced of Sir William White, the distinguished naval engineer, chief constructor of the British navy, president of the British Association. If his father had been chief constructor of the navy, he would have been included among Galton's noteworthy families of fellows of the Royal Society. The fact that his father-in-law was chief constructor of the British navy throws, if only by way of illustration, a light on the situation in two directions.

On the one hand, the specific character of performance and degree of success are determined by family position and privilege as well as by physical heredity; on

the other hand, marriage, chiefly determined by environment, is an important factor in maintaining family lines. The often-quoted cases of the Juke and Edwards families are more largely due to environment and intermarriage within that environment than to the persistence of the traits of one individual through several generations. The recently published "Kallikak Family" by Dr. H. H. Goddard demonstrates once again the heredity of feeble-mindedness. It would, however, have been a stronger argument for the omnipotence of heredity if the original ancestor had left by a healthy mother illegitimate children who established prosperous lines of descent, and a child by a feeble-minded wife who left degenerate lines of descent. Two experiments have been made on a large scale which seem fairly definite even though quantitative results can not at present be reached. The mulattoes may be assumed to have a heredity midway between negroes and whites, but their social environment is that of the negroes, and their performance corresponds with their social environment rather than with their heredity. Illegitimate children have perhaps a heredity as good as the average, but their performance falls far below the average. If performance were determined by heredity alone there might be expected to be among our thousand leading scientific men some forty mulattoes and some forty of illegitimate birth, whereas there is probably not one of either class.

At nearly the same time Agassiz came from abroad to Harvard and Brinnow to Michigan. We all know the list of distinguished naturalists trained under Agassiz—Brooks, Hyatt, Jordan, Lyman, Minot, Morse, Packard, Putnam, Seudder, Shaler, Verrill, Whitman, Wilder and many more, directly and indirectly. From Michigan have come, as is not so well known, one fourth of our most distinguished astronomers, including Abbe,

Campbell, Comstock, Curtis, Doolittle, Hall, Hussey, Klotz, Leuschner, Payne, Schaeberle, Watson and Woodward. Certainly the coming of Agassiz and Brünnow was the real cause of greatly increased scientific productivity in America. Some, but not all, of those who worked under Agassiz would have become naturalists apart from his influence. The astronomers from Michigan must in the main be attributed to their environment. The men had the necessary ability, but if Brünnow had not gone to Michigan, they would not have become astronomers; if they had gone to the University of Pennsylvania, they would have been more likely to become physicians than astronomers; if they had not gone to a university they would not have become scientific men.

It is certainly satisfactory if we can attribute the inferiority of scientific performance in America as compared with Germany, France and Great Britain to lack of opportunity rather than to lesser racial ability. In Germany scientific research has been made by the university rather than the reverse. In Great Britain also the universities have been potent, and, in addition, its leisure class has contributed greatly. Here prior to 1876 we had no university in which research work was adequately encouraged, and we have had no amateurs comparable to those of Great Britain. Professor Pickering found<sup>9</sup> that of the 87 scientific men who were members of at least two foreign academies, 6 were Americans as compared with 17 from Prussia, 13 from England and 12 from France. In so far as our scientific production is so measured, the reference is to a generation ago, when our universities were only beginning to develop and research work was only beginning to be appreciated. But it is a striking fact that of the six distinguished Americans, three are astronomers; and astronomy is the

only science in which thirty years ago the facilities for research work in this country were equal to those of the leading European nations. Of the remaining three, two have not been engaged in teaching, and the third has been practically freed from teaching for his research work. We may hope that when conditions become as favorable for other sciences as they have been for astronomy, the United States will assume leadership in scientific productivity.

In order to answer questions such as the extent to which the scientific work accomplished in America is due to native endowment, whether such endowment is general or specific, how far it occurs in family lines, what part of those endowed are able to prove their ability, the influence of education and example, the effects of opportunity, encouragement and rewards, it is necessary to make a study of individual cases. A large mass of material is at hand concerning the relatives of scientific men who have shown scientific productivity or have attained distinction, but these data are not in order for publication and should be supplemented by answers to many enquiries. In the meanwhile the writer may say that it is his opinion that while we should welcome and support a eugenic movement tending to limit the birth of feeble-minded and defective children and encouraging the birth of those that are well endowed, it appears that under existing conditions of knowledge, law and sentiment, we can probably accomplish more for science, civilization and racial advance by selecting from the thirty million children of the country those having superior natural ability and character, by training them and giving them opportunity to do the work for which they are fit. We waste the mineral resources of the country and the fertility of the soil, but our most scandalous waste is of our children, most of all of those who

<sup>9</sup> *The Popular Science Monthly*, October, 1908, and January, 1909.

might become men and women of performance and of genius.

Eugenics may become the most important of all applied sciences, but at present its scientific foundations must be laid by the study of comparative genetics, on the one side, and the study of human conduct, on the other. There is more immediate prospect of improving our civilization than our germ plasm. It is easier to decrease or eliminate typhoid fever by hygienic measures than to attain racial immunity, although this is not equally the case for tuberculosis and still less for cancer. We can increase to any desired extent from the existing population by proper selection and training the number of scientific workers in the United States. The number capable of exhibiting genius is limited, but many of them are lost through lack of opportunity. It is our business, it should be our principal business, to improve our civilization by giving opportunity to those who are fit, while at the same time investigating the conditions which will give us a better race.

## II. MARRIAGE AND NUMBER OF CHILDREN

There are thousands of volumes containing vital statistics, but exact studies of definite groups of individuals have scarcely been made. It is often assumed that we must have vast numbers of cases, such as are obtained by a national census, in order to secure valid statistics, but in some directions better scientific results can be obtained by applying more careful methods to a limited number of cases. The difficulty in obtaining correct statistics is not the variable error, which decreases with the number of cases, but the constant errors, which can only be eliminated by proper methods. Thus, for example, I find that the parents of 871 scientific men had families of the average size of 4.65 children, with a probable error of 0.05. The chances are even that increasing indefinitely the number of cases

would give a figure varying only between 4.6 and 4.7, and this is as close a determination as is needed. But a serious mistake would be made if it were assumed that the average family of the class from which the scientific men come was as large as 4.65. The fathers of 865 scientific men died at the average age of 70.6 years and their mothers at the average age of 70.2 years. The chances are even that this figure is correct within one third of a year, and this is all we need to know. It would, however, be incorrect to use these figures to prove that people of that class and generation lived to the age of seventy years or that the men lived longer than the women. In the census of 1880 there were found to be in the United States 170,000 more children in their second than in their first year. As over one tenth of all the children died in their first year, this result is incredible, and the large number of cases only makes the absurdity more obvious.

TABLE IV. NUMBERS AND PERCENTAGES OF SCIENTIFIC MEN WHO ARE UNMARRIED IN ACCORDANCE WITH THEIR AGES

Per cent . . .	18.00	10.45	7.06	9.16	6.25	10.5

The table shows that of just one thousand leading scientific men for whom the information is at hand 105 are unmarried. Eighteen per cent. of those under 40 years of age are single, 10.5 per cent. of those between 40 and 50, and 7.5 per cent. of those over 50. According to the census of 1900, 17.1 per cent. of men 35 to 44 years old are single, 10.4 per cent. of those from 45 to 54, and 7.8 per cent. of those from 55 to 64. There is thus a tolerably close correspondence between the marriages of scientific men and of the general population, but the age groups of the census

being five years older, a scientific man is more likely to be married than a man taken at random from the community. This is perhaps contrary to general opinion. A tradition of celibacy for the scholar has been inherited from the Roman Catholic Church, it being only within the time limits of these statistics that fellows of the colleges of the English universities have been permitted to marry. Professor Thorndike<sup>1</sup> found that only 12 per cent. of those in "Who's Who in America" over forty years of age are unmarried. On the other hand, President Eliot<sup>2</sup> found 28 per cent. of Harvard graduates 20 to 25 years out of college to be unmarried. There is a lack of satisfactory statistics of marriage conditions in different classes of the community. For different nations M. Bertillon<sup>3</sup> states the percentage of unmarried men over fifty years of age to vary from 16.3 in Belgium to 3.6 in Hungary, it being 7.5 in Germany and 10.1 in France.

Contrary to a wide-spread opinion, the marriage rate and the age at marriage have not varied considerably in the course of the past thirty years. The number of persons married annually for each thousand of the population in several countries has been as follows:<sup>4</sup>

	1881-1885	1910 (or 1909)
France.....	15	15.8
German Empire.....	15.4	15.5
Italy.....	16.1	15.5
England and Wales.....	15.2	15
Sweden.....	12.8	12

In England and Germany the rate was highest in the quinquennial period 1896-1900, reaching 16.1 and 18.8, respectively. The percentage of women between 15 and 49 years of age who are married has been:

<sup>1</sup> "Marriage among Eminent Men," *The Popular Science Monthly*, 1902.

<sup>2</sup> Annual Report of the President of Harvard College for 1901-02.

<sup>3</sup> "La Dépopulation de la France," Paris, 1911.

<sup>4</sup> Report of the Registrar-General (England and Wales) for 1910.

	1880 (or 1881)	1900 (or 1901)

Italy.....	55.2	56.1
German Empire.....	51.9	52.8
England and Wales.....	51.4	49.2
Sweden.....	41.4	44.2

There has thus been no decrease in marriage corresponding to the decreasing birth rate which has occurred during this period. In France, where the birth rate is the lowest, the marriage rate and the percentage of women married are the highest.

The marriage rate varies from year to year with economic and social conditions, but the percentage of women of child-bearing age who are married proves that marriage is as usual now as it was a generation ago. The conditions, however, are extremely complicated, being influenced by birth rates, death rates, the age constitution of the people and immigration. The European nations with the exception of France have supplied great numbers of immigrants during the past thirty years; these are largely people of marriageable age with an excess of unmarried men. This circumstance makes it more significant that there has been no decrease in marriage in these nations. It explains in large measure the relations in France and England, the latter country having been left with an excess in its population of over a million women above fifteen years of age. The comparatively high birth rates and death rates of a generation ago, followed by the decreasing birth rates and death rates which have obtained in nearly all nations for the past forty years, give a large percentage of the population between twenty and forty years of age, and are favorable to a high marriage rate and to a large proportion of married people. It is significant of improved conditions regarding the health of married women that among 900 scientific men only 15 are stated to have children by a second wife

and the number of children is only 29. The data also show that successive polygamy through divorce is unusual among scientific men.

the age of twenty-nine, 298 of the fathers and 328 of the mothers between twenty and twenty-nine. The scientific men themselves married at the average age of 29.5

In Table V. data are given in regard to the age at marriage and the size of family of our leading scientific men and of their parents.<sup>5</sup> The fathers married at the average age of 28 years and the mothers at the average age of 22.9 years. The median ages are naturally lower than the averages ages, as marriage can be postponed beyond the average longer than it can precede this average. The distribution of ages is also shown in the table. Five of the fathers and 85 of the mothers married under the age of twenty, 137 of the fathers and 27 of the mothers beyond

<sup>5</sup> The data are for the 440 cases in which the families of the scientific men were "completed" and in which there were no remarriages either of the scientific men or of their fathers. The families were taken as completed when the wife was 45 or older, when there had been ten years of married life without a child or when the period since the birth of the last child added to the mother's age is at least 45. Some of the families are then not absolutely completed, but the births would be very few. None of the 11 women who were more than 39 at marriage had children, although newly married women of this age are more likely than others to bear them. A larger error is due to the selection of families, as those having few or no children would be more likely to be completed. The 211 incomplete families have on the average 1.90 children, which is about the same as for the completed families of parents of the same age.

years and their wives were on the average 26.6 years old. The sons married about one and a half years later than their fathers and their wives nearly four years later than the mothers. There is a statistical anomaly in this comparison, especially as regards the mothers, for women who married late would have few children or none, and the average age of the mothers would thus be reduced as compared with the wives. The differences are partly due to the fact that all the scientific men and only part of the fathers belong to the professional classes; and there has probably been an increase in the age of marriage of the professional classes in this country; but the figures show that any such increase must be small.

Bertillon gives the following figures for the average age at marriage in the period 1896-1900:

	First Marriages		All Marriages	
	Men	Women	Men	Women
England.....	26.6	25.1	28.4	26.2

The age at marriage is highest in the Scandinavian nations; it is lowest in the Slav nations; it is as low in France, with its small birth rate, as elsewhere. In England in the case of first marriages the husband is one and a half years older than the wife, in France, nearly four and a half years older. The age at marriage for first marriages has increased in England by about three fourths of a year since 1896, before which date the registrar-general regards the records as inaccurate. The ages of the consorts at first marriages have increased from 26.59 and 25.08 in 1896 to 27.46 and 25.81 in 1911. The average age at which widowers marry has increased from 44.49 to 46.42; for widows from 40.58 to 41.74. In the quinquennial period 1876-80, 7.8 per cent. of the husbands and 21.7 per cent. of the wives were under twenty-one, in 1911 these percentages had decreased to 3.9 and 13.3. The professional and well-to-do classes marry later than the average; thus in England, the ages of the men and women are, respectively, about 32 and 27 years, as compared with about 26 and 24.5 years for the artisan and laboring classes. It thus appears that American scientific men marry at a somewhat earlier age than the professional classes in England and their wives are of about the same age.

The table shows that the size of family of the parents of the scientific men—the fraternity of the scientific men—decreases decidedly as the age of the mother at marriage increases. It is about five and a half when the mother is under twenty; it decreases to four and a half when she is between twenty-five and thirty and to scarcely over two and a half when she is between thirty and forty. The decrease would be somewhat greater if barren marriages were included; but it is altered in the opposite direction by the fact that the larger family has the better chance of giving birth to the scientific man. The decrease in the size of family with the

advancing age of the father is less, and depends mainly on the fact that older husbands are likely to have older wives. The age of the wife tends to increase about one year as the age of the husband increases by two years. According to the New South Wales statistics, admirably compiled by T. A. Coghlan,<sup>6</sup> the size of the family is five when the mother marries at 21, and as the age at marriage increases to 24, 28 and 32, the size of the family decreases to approximately four, three and two. In the case of the scientific men the family is 2.59 when the mother was 20 to 24 years old at marriage and 2.44 when she was 25 to 29. It is only two in the fifteen cases when she was under twenty. A comparison of these figures with those for the larger families of the preceding generation is significant, as they seem to show the condition when the family is small and limited. Under these circumstances there is but slight difference in the number of children when a woman marries at ages from 15 to 29. After thirty, however, there is a marked decrease, the size of family being 1.6 for women marrying between 30 and 34 and only 0.6 for those marrying between 35 and 39. Less than half of those marrying between 35 and 39 had children and none of those who married at the age of 40 or older had children.

The families from which our scientific men come had on the average 4.7 children, and those scientific men who are married and whose families are complete have on the average 2.3 children, these figures including all the children born. Sir Francis Galton<sup>7</sup> found that a group of about 100 English scientific men (excluding barren marriages) had, on the average, 4.7 children, and their parents 6.3, and remarks: "This implies a diminution of fertility as

<sup>6</sup> "The Decline in the Birth Rate of New South Wales," Sydney, 1903.

<sup>7</sup> "English Men of Science," London, 1874, New York, 1875.

compared with that of their parents, and confirms the common belief in the tendency to an extinction of the families of men who work hard with the brain." Mr. Havelock Ellis<sup>s</sup> found that 214 fertile marriages of British men of distinction produced, on the average, 5.45 children, while 276 "genius producing families" consisted, on the average, of 6.96 children, and remarks that "men of genius belong to families in which there is a high birth rate, a flaring up of procreative activity." He says further that this "might, indeed, have been anticipated. The mentally abnormal classes generally belong to families with a high birth rate"; and quotes data in regard to criminals and the insane. Thus two wide generalizations—that intellectual performance conduces to sterility and that genius is allied to insanity—are based on a curious statistical fallacy for which one would suppose Galton the least likely of men to be responsible.

In a population whose families remain of the same average size in successive generations, every one, whether he be a scientific man, a criminal or a tailor, is likely to come from a larger family than he has. If, for example, all families were of one or of seven children equally divided, the average family would be four in each generation, but the children would be seven times as likely to come from the larger family and would belong to a family which, on the average, would be 6.25. With an average family of three, the size of 100 families would be distributed approximately as follows:

Size ..	0	1	2	3	4	5	6	7	8	9	10
No. ..	18	10	20	23	15	7	5	3	2	1	1

When then we count up the average size of the family from which each of the 300 children comes, it will be found to be 4.47. As our scientific men come from families of the average size of 4.7, one may conclude that the families of the class to which they belonged were of the average

<sup>s</sup>"A Study of British Genius," London, 1904.

size of about 3.2. In one generation this family has been reduced to 2.3, owing either to a general fall in the birth rate or because scientific men have families which are smaller than those of the classes to which their parents belonged. Both factors are present; there is a general decrease in the birth rate and the educated classes have families smaller than the average.

In Table VI. is given information in regard to the size of family of the parents of scientific men in accordance with their nationalities and their occupations. The Germans had families of the average size of 5.7, the British of 4.8 and the native Americans of 4.5. The probable errors show that these differences are not due to the limited number of cases. It is known that immigrants from foreign nations have larger families than native

Americans, but these figures probably give the only information in regard to the families which produce scientific and other professional men. The disparity is not so great as in the so-called lower classes, but it is sufficient to indicate that in the professional classes descendants of recent immigrants from Germany and Great Britain

will in part supplant the descendants of native Americans. It is, however, the case that immigrants are likely to become assimilated to native Americans in size of family as well as in other respects.

The parents of scientific men from the agricultural classes had families of the average size of 5, those engaged in manufactures and trade of 4.6 and those in the professions of 4.5. It was shown in the previous section that the agricultural classes contribute in proportion to their numbers only one thirtieth as many scientific men as the professional classes, and this disparity is increased by their larger families. Among the professions, physicians had the smallest families and clergymen the largest, but the differences are not large, the family of the clergyman being smaller than the family of the farmer. These figures do not, of course, give information in regard to families of the present generation, in which the differences are probably greater.

In Table VII. are given the figures for the children of the scientific men in accordance with their nationalities. The

Americans have, on the average, a family of 2.19 children, the British of 2.43 and the Germans of 3.21. The German family is thus nearly 50 per cent. larger than the American. The number of foreign families is, however, too small to give valid averages. It would be very desirable to obtain information in regard to the size of family and other vital statistics for different nationalities and social classes in our population. A single expert in the Bureau of the Census could collect and collate such data in the course of a couple of years at insignificant expense.

Table VIII. gives the sizes of the families from which the scientific men have come and which they have in accordance with the geographical division in which they were born and in accordance with whether they were born in the country or in the city. The differences are small. When the parents lived in the country or in small places at the time of birth of the scientific men, they had on the average 4.68 children; and when they lived in the towns which in 1900 had a population of 25,000 or over, the size of family was 4.43. The scientific men born in the country had on the average 2.31 children, those born in towns, 2.15. As it will take a long time to correct the common idea that children born in the country are more likely to attain success and distinction than those born in cities, attention may again be called to the fact that about one fourth of these leading scientific men were born in cities having in 1860 about one

eighth of the population of the nation. The greater productivity of cities in men of distinction is doubtless in part due to the fact that the abler and more enterprising people are drawn from the country to the cities, their children inheriting superior ability, and in part to the fact that the city-born children have an environment more favorable to education and to success in scientific work.

The number of families from the southern and western states is too small to give reliable information in regard to the number of children. The fraternities of the scientific men from the North Central States are larger than of those from the North Atlantic States, but their own families are smaller. The differences are small, but apparently significant. The scientific men born in the North Central States came from families of 5.0 and had families of 2.2, those from the North Atlantic States came from families of 4.4 and had families of 2.3. A generation ago the families of the central States—at least those of this particular class—were larger than those of the Northeastern States; they are now slightly smaller. The fertile and wealthy state of Iowa had a smaller population in 1910 than in 1900. The increase in the population of the country is maintained by immigrants and the children of immigrants. The 87 scientific men born in Massachusetts had fraternities of 4.1 and families of 2.1 children, the 117 born in New York State had fraternities of 4.5 and families of 2.3 children.

The table shows the great preponderance of the North Atlantic and North Central States in the production of scientific men and the infertility of the south, concerning which statistics have been given by the writer in previous articles. The birth rate of leading scientific men per million of the population has been 107 in Massachusetts, 89 in Connecticut, 47 in New York, 23 in Pennsylvania, 32 in Ohio, 36 in Michigan, 45 in Wisconsin, 24 in Illi-

nois, 12 in Missouri, 9 in Virginia, 5 in North Carolina, 3 in Georgia, 2 in Alabama, 1 in Mississippi and Louisiana. In recent years, however, the North Central States have been gaining and the North Atlantic States have been relatively losing. Thus for younger men the birth rates in figures comparable to those given above have fallen to 85 in Massachusetts, 57 in Connecticut and 36 in New York, whereas they have risen to 35 in Ohio, 74 in Michigan and 54 in Wisconsin. These differences and changes the writer is disposed to attribute in the main to environment rather than to heredity. From the family stocks of Massachusetts, Michigan or Louisiana, we can obtain as many competent scientific men as we care to educate and support.

The distribution of the families among different kinds of institutions is given in Table IX. The fraternities of the scientific men are substantially the same in all cases. The only instance in which the departure from the average exceeds the probable error is for the smaller state-supported institutions, and the difference here may not be significant. In the case of the children of the scientific men, the size of family is probably influenced by the environment. The 73 men in the government service, most of whom live in Washington, have the smallest families, those in the smaller state-supported institutions the largest. The probable errors

of the figures are about 0.1, so the differences are not likely to be due to chance. The 61 men in commercial work, or having no institutional affiliations, and the 56 men in research and related institutions have families larger than the average, while those in the larger universities have families smaller than the average. In the larger private universities the situation, for those with 10 or more professors who supplied the information, is: Harvard, 42 families with an average of 2.2 children; Yale, 16 and 2.0; Chicago, 25 and 2.1; Johns Hopkins 12 and 2.1; Cornell, 29 and 2.3; Stanford, 13 and 2.4; Princeton, 10 and 2.5; Pennsylvania, 13 and 2.5; Columbia, 25 and 2.7. The smallest families are at Yale, Johns Hopkins and Chicago, the largest at Princeton, Pennsylvania and Columbia. The larger state universities have professors with the smallest families, the size of family being Michigan, 17 families with an average of 2.1 children; Minnesota, 10 and 1.8; Wisconsin, 15 and 1.7; Illinois, 15 and 1.6

The figures given are for completed families and for all children born. The death rate for the children of scientific men is unusually small, 75 per thousand to the age of five years and about 120 to the age of marriage. The marriage rate for scientific men is high, 895 among the thousand being married. None the less it is obvious that the families are not self-perpetuating. The scientific men under fifty, of whom there are 261 with completed families, have on the average 1.88 children, about 12 per cent. of whom die before the age of marriage. What proportion will marry we do not know; but only about 75 per cent. of Harvard and Yale graduates marry; only 50 per cent. of the graduates of colleges for women marry. A scientific man has on the average about seven tenths of an adult son. If three fourths of his sons and grandsons marry and their families continue to be of the same size, a thousand scientific men

will leave about 350 grandsons who marry to transmit their names and their hereditary traits. The extermination will be still more rapid in female lines.

If the families of the scientific men should increase at the rate of the general population, the thousand leading scientific men would have some 6,000 grandchildren instead of fewer than 2,000. These well-endowed and well-placed people would probably have an average economic worth through their performance of not less than \$100,000, and the money loss due to their non-existence is thus \$400,000,000. The loss to the welfare of the nation and the world from the suppression of the social traditions and the germplasm is incalculable. Until democratic society learns that services for society must be paid for by society, and that the two most important services are scientific research and the bearing and rearing of children, the universities, on which three fourths of our scientific men depend for support, have great responsibilities. They to a certain extent profess that research is part of the work for which their professors are paid, but they do not acknowledge a similar obligation in regard to the children of professors. Columbia University gives, under certain faculties, scholarships to the sons of professors; Yale University has had a statute by which a married professor received a slightly increased salary; the provisions of the Carnegie Foundation benefit married professors. But these are slight acknowledgments of the obligations of our universities.

President Eliot tells us that "the welfare of the family is the ultimate end of all industry, trade, education and government"; but, in his book on "University Administration," he writes:

The general features of a good scale of salaries are as follows: The salary of an annual appointee at the start should be low, about the amount needed by a young unmarried man for comfortable support in the university's city or village. When,

after a few years, this young man receives an appointment without limit of time, a somewhat higher salary should be given him, with a small advance each year for, say, three years. If this instructor so commends himself that the university desires his further service, he should receive, as assistant professor, a salary which will enable him to support a wife and two or three children comfortably, but without luxury or costly pleasures.

The scientific man receives his doctorate at the average age of twenty-seven years and is then eligible for an instructorship with a salary for an "unmarried man"; after "a few years" and then "three years" more he is to receive a salary which will enable him to support "two or three children." President Eliot also says:

The recent tendency of sons of well-to-do, and even rich, families, to go into the ministry, the medical profession, academic life, and the public service, is one in which all patriots may well rejoice. . . . It is a good deal safer to give a life office to a married man on whom marriage has proved to have a good effect, than to a single man who may shortly be married with uncertain results.

There might well be inscribed at Harvard and at other universities the words which President Eliot wrote for the Water-Gate of the Chicago World's Fair, changing one word, so that it would read:

TO THE  
BRAVE WOMEN  
WHO IN  
UNIVERSITIES  
AMID STRANGE  
DANGERS AND  
HEAVY TOIL  
REARED FAMILIES  
AND MADE HOMES

The vital statistics of the United States are entirely inadequate. Where registrations of deaths and births exist, they are imperfect, and the changing population, its age composition and the amount of immigration render them difficult to interpret. The only information concerning birth rates is given by the proportion of children as determined by the census,<sup>10</sup>

<sup>10</sup> In January, 1917, was issued the first bulletin from the Bureau of the Census giving birth rates for ten states.

but even this is unreliable. It might be supposed that it would be possible to determine the number of children by counting them, but this is not the case. The children reported in the census of 1850 were fewer than the survivors (with the comparatively small excess of immigrants) counted ten years later. There are always more children given as two years old than as one—in 1880 as many as 170,000 more. Nor can we have complete confidence in the compilations of the experts of the census. Thus in the case under consideration they give<sup>11</sup> figures

FIG. 1. Ratio of white adults of self-supporting age to white children under sixteen years in the United States, according to the Bureau of the Census.

<sup>11</sup> "A Century of Population and Growth," Bureau of the Census, 1909, pp. 80 and 103. An answer to a letter addressed by the writer to the director of the census partly explains the way this error was committed—but the explanation was marked "confidential"! It is, however, no violation of this confidence to state, as the information is available from official reports, that figures were not at hand prior to 1830 and that these were guessed—it appears very awkwardly—so as to give a regular curve.

showing that the white population of the United States increased from 1790 to 1800 by 35.7 per cent., adults over 20 by 50.9 per cent., and children under 16 by 38.8 per cent., whence it follows that children from 15 to 19 decreased 22 per cent. This is of course absurd and is due to a gross error of some sort. However, the ratio of white adults twenty years of age and over to white children under 16, according to the census reports, is shown on the curve. The percentage of children under 16 years of age in the white population increased from 1790 to 1810 and was the same in 1820 as in 1790. In 1810 just half the white population consisted of children under 16; in 1900 the percentage of children had decreased to 35.7.

From a special study by Mr. Kuczynski,<sup>12</sup> it appears that the birth rate of the native population of Massachusetts has been 63 per thousand women of child-bearing age, as compared with 85 in France, 104 in England and 143 in Russia. Its birth rate per thousand of the population was 17, the size of family 2.61 and of the sur-

living family 1.92. Special statistics have been gathered for college graduates. President Eliot in his report for 1901-02 stated that 634 married Harvard graduates of the classes from '72 to '77 had an average family of 1.99 surviving children. Only 71.9 per cent. of the graduates were married, and the number of children for each member of the class was 1.43. If only 72 per cent. of Harvard graduates are married at the average age of fifty, it is a serious indictment of the kind of men who go to Harvard or of the influences under which they come. We have seen that 91 per cent. of American men of science over 40 are married. Other data concerning the families of college graduates have been published by Professor Thorndike<sup>13</sup> and others.

Curves are here drawn for some of the data, which show that the gross size of the family of college graduates has decreased from 5.6 at the beginning of the century to 2.5 for classes graduating in 1875, while at that time the size for Harvard was about 2. A projection of these curves—which of course gives no scientific information—shows the curious result that if the decrease should continue at the same rate students graduating in 1835 would have no children. The average college graduate has a family of about the same size as the scientific man of the same age. Data collected for the graduates of Yale,<sup>14</sup> in the classes 1869-86 twenty years after graduation and thus not quite complete, give the following results for different occupations:

Graduates of colleges for women also have had families of about two, but half of them remain unmarried. The Harvard graduate thus has on the average three fourths of a son, the Vassar graduate one half a daughter.

Since this article was written and published in abstract elsewhere,<sup>15</sup> there have appeared two excellent articles on the size of family of college graduates. Johnson and Stutzmann<sup>16</sup> find that about half of Wellesley College alumnae graduating from 1879 to 1888 married and had families averaging 1.56 children. John C. Phillips<sup>17</sup> gives data from the class reports of Harvard and Yale students compiled twenty-five years after graduation. Seventy-four per cent. of Harvard graduates and 78 per cent. of Yale graduates had married. The number of children born for each married graduate decreases from about 3 in the fifties to 1.8 in 1890. As Mr. Phillips points out, the decrease becomes slower between 1875 and 1890.

In Table X. it is shown that the families of scientific men in which the mothers have had a college education are not appreciably smaller than others. If one regards only the total, it appears that when

the mother had a college education the average family is about 2, when she had a partial college education 2.1 and when she had none 2.3, but these differences are chiefly and probably entirely due to the fact that the younger scientific men have the smaller families and at the same time are more likely to marry college graduates. If we divide the scientific men into three age groups, the differences become much less, and if the groups were subdivided still further they would probably disappear. This illustrates the possibility of statistical fallacies when a group is not homogeneous. Of the scientific men under fifty, 109 married college graduates and had families of the average size of 1.81, 33 married women with a normal school or partial college education and the average family was 1.79, 119 married women without a college education and the average family was 1.98. Fifty-four per cent. of scientific men under 50 have married women with a college education; for scientific men from 50 to 59 the percentage falls to 35 and for those 60 or older to 19.

The figures result not only from the increasing number of women undergoing higher education, but also from an extension of common scientific interests and pursuits for men and women. A distinguished biologist has observed that "if marriages are made in heaven, Woods Hole may be regarded as a branch office." To the same biologist we owe the remark that "eugenics is an infant industry." There is truth in both epigrams. The percentage of men who have married women with whom they have been thrown into association as teachers or fellow students is large, and we are at present ignorant of the results of such marriages. Small as are the families of scientific men, it is here shown that they are not so because the mother is a college graduate. If both mother and father have common scientific aptitudes and interests, the physical heredity and social traditions should lead

the children to follow similar scientific pursuits with an early start and favorable opportunities. I shall be able to give the percentage of fathers and sons, or of two or more brothers, who have engaged in scientific work, and it may be possible to determine the effect when the mother also has scientific interests and ability.

### III. VITAL STATISTICS AND THE COMPOSITION OF FAMILIES

It has been claimed that children of older parents are physically and mentally inferior. Conversely, C. L. Redfield in a curious book entitled "Control of Heredity" and in various articles argues that men of distinction are likely to be born when their fathers are old and that their performance is due to inheritance of the experiences gained by their fathers. If the age of the parents affects the constitution of the children, this clearly is a matter of importance, particularly if the principles of eugenics are enforced either by law or by sentiment. But at present we have no scientific information on a problem which could be solved by statistical research.

The fathers of 865 leading American men of science were on the average 35 years old and their mothers were 29 years and 8 months old when their sons were born. The fathers married at the average age of twenty-eight years, being somewhat more than five years older than their wives. The scientific men are consequently born at an average interval of seven years after the marriage of their

parents. The ages are given separately for the four groups into which the scientific men have been divided and are earlier for both fathers and mothers (group I. in the table) of those more distinguished. The probable errors given in italics show that the differences may be due to chance, but that this is unlikely. It is the case, as shown below in Table XIV., that the first-born son is the one most likely to become a scientific man, and the parents of first-born children are of course younger.

In Table XI. is also given the average age at death of the parents, whence it appears that the fathers died at the average age of 70.6 years, the mothers at 70.2 years, the chances being even that these figures are correct within a third of a year. The average age of the scientific men being about fifty years, most of their parents are now no longer living. If, however, the deceased parents only had been included, the averages would have been too low, as the more long-lived parents would be those more likely to be living. The expectation of life has been added to the age of each of those still living, and the probable age at death used in the averages. The ages given do not mean that people of this class live to those ages, or that the men live longer than the women. A statistical error such as this has often been made, a distinguished scientific man having, for example, urged that it is one of the advantages of the scientific career that scientific men live much longer than the average, failing to note the circumstance that there are no scientific men who die

when they are babies. The figures in the table mean that the fathers being on the average 35 years old when their sons are born have an expectation of life of 35.6 years, and will on the average die at the age of 70.6 years. The mothers, averaging 29.7 years old, have an expectation of life of 40.5 years. These expectations are about four years longer than those allowed by standard mortality tables, but the data are not exactly comparable. Although the parents of the more distinguished scientific men do not live longer than the others, they live longer after the births of their sons.

Table XII. shows that the farmers who were fathers of scientific men died at the average age of 72.8 years, the physicians at 67.2 years, a difference of over five years between the shortest and longest lived of the groups. The clergymen and lawyers lived one year less than the farmers, the teachers two and a half years less. Those engaged in manufacturing and trade died at the average age. According to the report of the English registrar-general (1908), the death rates per thousand during the years 1900-1902 for those

between 45 and 65 in different occupations were: Farmers, 14.8; clergymen, 15.5; teachers, 15.8; lawyers, 18.3; physicians, 23.9.

Table XIII. gives the ages at death of the mothers in accordance with the size of their families. The crude figures are subject to a statistical error, as mothers might have small families because they died early. This is eliminated by considering only those who survived the child-bearing age. In this case mothers of one child died at the average of 68.6 years; mothers of 12 children at the age of 80.6. There are included 759 families, but the number of families of different sizes is too small to give entirely valid averages. Still it is significant that the thirteen mothers of 11 and 12 children lived to the average age of 78 years; the 43 mothers of 9 and 10 children to the age of 75 years. It is probable that the women who were the more vigorous had the largest number of children and also lived to the greatest age; they might have lived as long or even longer if they had been unmarried. Though largely due to statistical selection, the fact remains that of 45 mothers of one child 10 did not survive the age of 45, whereas of 56 mothers of from 9 to 12 children not one died under this age. In view of these facts it may be doubted whether the practise of limiting the number of children is beneficial to the health and longevity of the mother.

Table XIV. gives the numbers of scientific men who were first-born children, second-born children, etc., for each size of family. A scientific man is of course more likely to be a first-born child than a second-born, because there are families with

only one child and consequently more first-born children. But it appears from the table that the first-born child is more likely than the others to become a scientific man. In families of two or more children, 284 are first-born and only 168 second-born; in families of three or more, 214 are first-born and 114 are third-born; in families of four or more, 159 are first-born and 81 fourth-born.

The first-born child has been reported to be more likely to be a man of genius, an idiot, a consumptive and various other things, but usually as the result of some statistical fallacy. If, for example, in our figures only families of two and eight are considered, there being on the average five children and one first-born, it looks at first sight as though the chances are one in five that an individual selected at random would be the first-born. But both families being represented, it has been argued that the chances are half that the individual is the first-born in the small family and one eighth in the large family, or on the average five sixteenths, nearly one in three. However, the family of eight is four times as likely to be represented in a random selection from the two families, so the chances of the individual being first-born are reduced to one in five. Finally—and this seems to have been

overlooked—there are three times as many families of two as of eight, and there are in fact 16 chances out of 61, or a little over one in four, that the individual selected at random will be the first-born.

These errors have been eliminated by the method used in the table, but there are at least two other statistical errors that affect such data. When we are dealing with contemporary families the older children may be preferred. Thus children under fifteen are not likely to suffer from pulmonary tuberculosis or to be criminals, and the patient or the prisoner may be more likely to be the first-born child than the last born. This circumstance holds for the scientific men. They are on the average 38 years old when they attain their position, and the scientific population is rapidly increasing, so the earlier born children are more likely to be included. This factor, however, is small, as is shown by the fact that the second-born child is not appreciably more likely to be a scientific man than those later born. Probably a large statistical error is introduced by the fact that a man sometimes does not know of or ignores children who were born and died before he himself was born, and thus records himself as the first-born.

In so far as it may in fact be the case that the first-born child is more likely to be a scientific man, this is probably due to social rather than to physiological causes. Galton found the eldest son to be preferred, and perhaps this might be expected under a system of primogeniture. In this country where families are apt to improve their economic condition, the younger sons may be more likely to be sent to college than the older, but as to this there is no available information.

In Table XV. the intervals are given between marriage and the birth of the first child and between the births of successive children for families of different sizes. When there is only one child it is born on

the average 3.2 years after marriage, whereas in a family of five or more the interval is about a year and a half. In the standardized family of two the second child is born 4.2 years after the first, twice as long as for large families. The delay in the birth of children in small families might be due to the same physiological or pathological causes which make the family small, but in most cases it is probably due to voluntary control.

From Table XVI. it appears that 478 scientific men reported 716 sons and 668 daughters. This difference falls within

the limits of chance variation, and is not likely to be significant. In the families from which 832 scientific men come there were 2,537 sons and 1,527 daughters recorded. This disparity may at first strike the reader as inexplicable. Galton in his "Hereditary Genius" says: "I also found the (adult) families to consist on an average of not less than  $2\frac{1}{2}$  sons and  $2\frac{1}{2}$  daughters each. Consequently each judge has on an average of  $1\frac{1}{2}$  brothers and  $2\frac{1}{2}$  sisters. . . . 100 judges are supposed to have 150 brothers and 250 sisters." Nearly all those whom I have questioned about this statement think that it is correct. It seems to most people obvious that if there are equal numbers of boys and girls, a boy must on the average have one more sister than brother. However, a boy has as many brothers as sisters, owing to the sex composition of families. Thus in families of two, one fourth of the families will consist of two boys, one fourth of two girls and one half of a boy and girl. On the average, four boys will have among them two brothers and two sisters, and there is a similar equality for large families.

Table XVII. contains information in regard to deaths in the families of scientific men. For their brothers and sisters the percentage of deaths recorded under five years is 14.8, and under twenty-five years it is 22.5. For their children the percentages are 7.5 and 10.9. The death rate has thus decreased to half in a single generation, and for the children of the scientific men is probably the smallest known. As only completed families are

considered, there are practically no children under five, but those under twenty-five who might die before reaching that age make the death rate too low in this

group. It is difficult to see how more valid statistics can be obtained than those supplied by scientific men, the order of birth and the dates of birth and death having been given; yet it is undoubtedly the case that all deaths are not recorded, especially for the brothers and sisters who died in infancy. This error would, however, only emphasize the decrease in the deaths of the children as compared with the preceding generation. The number of deaths among a thousand children born is not directly comparable with death rates per thousand of the child population. When there are seventy-five deaths under the age of five among a thousand infants born to the scientific men, the annual death rate is somewhat larger than 15.

The decrease in the infantile death rate in recent years is so remarkable as to be almost incredible, and the existing differences in nations and social classes are appalling. In the families from which our scientific men come, the death rate for children under five is somewhat over 30 and in their own families it is somewhat over 15. The rate in the registration area of the United States in 1900 was 51.9. In the present registration area it was 32.9 in 1911, varying from 41.1 in Massachusetts to 18.6 in Washington, from 74 in

Fall River to 22.4 in Seattle. In or about 1900, the rates for the other nations were:

Russia . . . . .	134.5
Spain . . . . .	104.1
Austria . . . . .	86.7
Germany . . . . .	74.2
Italy . . . . .	74.8
England . . . . .	53.5
France . . . . .	47.6
Sweden . . . . .	37.5
New Zealand . . . . .	23.2

The table indicates a small selective death rate against the larger families. When there were one to six brothers or sisters the percentage of deaths under five years was 14.2 as compared with 15.6 for larger families; when the number of children was four or less, the percentage was 7. as compared with 8 for families of five or larger. This small difference is probably due to the coinciding decrease in the birth rate and in the death rate. The larger families had a higher death rate not because they were larger but because they were earlier when the death rate was higher. Other statistics, such as those of Labin and Westergaard for Copenhagen, show a selective death rate against the larger families. In the statistics with which we are concerned poverty and neglect are almost excluded.

In Table XVIII. is shown the relation between the size of the family from which the scientific men come and the size of the family that they have, the scientific men being divided into three age groups. It will be noted that the size of family of the scientific men varies with their age at the time, being 2.7 children when they are above 59; 2.3 when they are between 50 and 59, and 1.9 when they are under 50. These differences are partly due to statistical selection, the families of the younger men being not absolutely complete, and the barren and smaller families being more likely to be included. They, however, in part represent the declining birth rate within a period of twenty years. There is

shown a slight positive correlation between the number of brothers and sisters and the number of children. Thus when a man comes from a family of 1, 2 or 3 children, his family averages 2.1, and as the size of the family from which he comes increases by groups of three, his own family size increases to 2.2, 2.3 and 2.8. The probable errors show that the figures have a limited validity. The differences, however, may be due to the decreasing size of family, the older scientific men having larger families and coming from families which were larger because they were earlier. The inheritance of physiological fertility would depend partly and perhaps chiefly on the female, and the size of the modern small family is determined in the main by social and psychological causes. If the data here given were valid, they would show a slight correlation of fecundity in successive generations and a slight selective death rate against the larger family, which about balance each other. These conditions are those which must obtain in a state of nature, for unless there is a change in the environment, the number of individuals of a species can not considerably increase and if they regularly decrease it will be exterminated. The relations which obtain in the families of scientific men are, however, probably due entirely to the decreasing death rates and birth rates of the past seventy-five years.

In Table XIX. the scientific men are divided into four groups in accordance

with their distinction, and the size of the family from which they came and which

they have is given for each degree of distinction. The most distinguished group (I. in the table) came from families of the average size of 4.7 and have families of the average size of 2.5, in both cases above the average. The eminent man is slightly more likely to have more brothers and sisters and appreciably more likely to have more children than his colleagues. The most eminent group is, however, about five years older than the others, and this about accounts for their larger families, no rapid has been the decline in the birth rate. The lack of correlation between the distinction of a scientific man and the size of his parents' family may be due to a combination of causes. On the one hand, only child or the child from a small family may be more likely to have educational opportunities or inherited wealth; the other hand, he may have inferior heredity and opportunity for forming character.

The conditions are similar for scientific

men who are unmarried or who have no children or but one, as compared with scientific men with larger families. There is but slight difference in their performance. The similarity may be due to a balance of various conditions, and is also in part accounted for by the fact that men marrying at the average age of 29.5 years have in large measure had such original ideas as they may hope to have and have in the main determined their careers. As a matter of fact those who are unmarried

with the largest families could be regarded as valid, it would be indicated that the

are the ablest and most successful, but there is a biological adaptation which at the same time furnish the largest share of the group who have dropped out of the first thousand, perhaps owing to the circumstance that scientific work must be neglected to support the children. The decrease of the average family to three or four—in the case of American scientific men or college graduates to two—must be due to infertility or to voluntary limitation. Both causes have been recognized since the time of the writing of the book of Genesis; both have doubtless increased in force in the course of the nineteenth century. It is generally believed that the principal cause of the small size of the modern family is voluntary limitation. A definite answer is supplied by information given to me by 461 leading scientific men, as shown in Table XX.

Of these completed families 176 were not voluntarily limited, while 285 were so limited.

<sup>1</sup> From an article printed in the *Independent*, September 27, 1915, being the abstract of an address given at the First National Conference on Race Betterment. The writer had at that time made an extensive study of vital statistics, with special reference to birth-rates and related problems, but the collection of such statistics has been interrupted and their interpretation made difficult by the war.

ited, the cause of the voluntary limitation being health in 133 cases, expense in 98 cases and various other reasons in 54 cases. Childlessness was involuntary in two thirds of the cases. In the standardized family of two children the condition was desired six times out of seven. In over one third of the 461 families the limitation was involuntary, due to infertility and other pathological causes, but if these had not obtained, voluntary limitation would have oc-

curred later in nearly all cases. In seventy-one marriages prior to 1890 the average size of family including all children born was 2.9, and the limitation was voluntary in forty-eight per cent. of the cases. In the decade of the 80's with 132 marriages the size of the family was 2.6, and the limitation was voluntary in sixty-four per cent. of the cases. For 198 marriages contracted in the 90's, when no more children will be born, the average size of family was 2.0, and the limitation is voluntary in seventy per cent. of the cases.

FIG. 4. The number of families of American men of science of each size, showing the number voluntarily limited and the causes of the limitation.

Neither the prevalence of the voluntary limitation of the size of family, nor the fact that the size of family is limited directly or indirectly through infertility or ill-health in more than three fourths of the cases, can be regarded with satisfaction. It is indeed evident that a limitation of the number of offspring was an essential condition of the evolution of a higher race at all of the civilization to which it has attained. It might be as undesirable and benighted as illegal for a man to have six children as to have two wives. But we are laying with edged tools when we substitute rationalism for fundamental instincts. In practice the family is not voluntarily limited for the welfare of the race, but to avoid risk and ill-health—real or fancied—expense and inconvenience, and to give the individual child greater advantages. There seem to be no existing conditions which will check the decreasing birth rate, while there are powerful forces tending to its decline below the danger point of the death rate.
